.0: yaln düğün mağazaları-düğün mağazaları? pdfs, symbols, and authorless PDFs For years, I've been using an authorless PDF, generated by a program named Rfpdf. The basic idea is to be able to create a PDF from your R script, and to make the PDF useful to the end user in a number of ways. Rfpdf is, of course, inspired by an idea first put forward in the 1980s: that you can use XML to encode an arbitrary document. The code that does the encoding is written in the R programming language, so it is possible to write a complete document without any mark-up or formatting. You can write the code directly into your R script, without using a word processor. At the moment, Rfpdf does not deal well with tables; you have to create a block in XML that is not R-specific. I started using Rfpdf in 2007, and in 2009 I started to work on a new version of Rfpdf. In 2010, I put the new code on the CRAN web site and got over a thousand downloads. (It's not yet a CRAN package, and I think I'm still in the licensing purgatory that is the first version of any new open source project. In the meantime, I've received three different requests for commercial licenses.) I also came across pdfX in the process. pdfX is an extension to the XML family of formats, including XHTML and XForms. The difference is that pdfX is for authorless documents. As pdfX is written in C++, you need to link with libpdf, the C++ pdfX library. pdfX was written by the same Ian Hickson who wrote the DOM in HTML 5, and it is well thought out. pdfX allows you to define an XML file, and then write code in C++ to generate the actual PDF. pdfX's success is interesting, because it demonstrates that it's possible to create PDFs from any type of programming language. At the moment, authorless PDFs have limited use. A book is the most useful form of authorless PDF, and I write most of my books this way. The chief issue is that authorless PDFs are, well, free-form documents, and are hard to format. In future, it seems likely that 82157476af
